Abstract

Visual P300 responses were recorded by using checkerboard-type stimuli. (1) High amplitude P300-delta responses were visible even in single trial ERPs. (2) An algorithm for efficient selection of P300 single trials (based on evaluation of delta responses) is introduced. (3) The 'universal' character of the P300-delta response demonstrated in this report may open new avenues for the understanding of functional ERP components. © 2001 Elsevier Science B.V. Keywords: EEG; P300; ERP single trial analysis

1. Introduction

In earlier works it has been assumed that event-related potentials (ERPs) arise by superposition of event-related oscillations in several frequency ranges. These frequency ranges, in turn, are almost similar to the natural EEG frequen-

cies as manifested in the spontaneous EEG (Başar, 1980).

In this context, the question arises whether event-related oscillations of a certain frequency can be isolated from ERPs, in particular from single-trial ERPs. More specifically, can these frequency responses be related to certain aspects of stimulus processing in the brain? The present article addresses both questions with respect to the psychophysiological role of the delta response.

To elicit such delta responses, we performed EEG measurements in healthy adults, using an oddball paradigm with visual stimuli. The P300

Abbreviations: ERP, event-related potential; EHF, enhancement factor.
